SUMMARY

Delamination Growth in Composites under Fatigue Loading

By

Rafiullah Khan

Fiber reinforced composites are attractive for aerospace applications due to high specific strength and stiffness. Their use has been gradually increased to 50% by weight of the aircraft over past decades. As a consequence, modern aircraft utilize composites in the primary structures like wing skin and fuselage. The use of composites in primary structures has increased the need for reliable strength assessment methodologies.

Composites are inherent to various damage types of which delamination is the most severe type of damage. Delaminations may grow due to fatigue resulting in the stress redistribution and potentially leading to structural failure, thus making fatigue an important design concern.

Damage tolerance of aircraft structures is a key aspect in maintenance and safety of aircraft. For damage tolerant design of structures, the development of accurate delamination growth assessment tools is necessary.

Delamination growth is affected by both cyclic and monotonic part of the fatigue load cycle. The effect of monotonic part is known as stress ratio (ratio of minimum to maximum cyclic stress) effect on delamination growth, and it has been extensively studied in the literature. Chapter 2 provides a detailed review of the literature concerning the stress ratio effect on delamination growth.

The literature review shows that previous studies empirically relate delamination growth to a driving force parameter that seems not based on physical mechanisms. Studies are present where mechanisms of delamination growth have been investigated; however there is a lack of efforts to link these quantitatively to delamination growth models.

The objective of this thesis is the development of a mechanistic model for delamination growth that is based on the observed delamination mechanisms and the effects of monotonic and cyclic loadings in fatigue. The thesis is based on the hypothesis that both monotonic and cyclic loading affect fracture surface formation, which can be used for delamination growth characterization. The secondary objective of the thesis is the characterization of fracture surfaces for the effect of monotonic and cyclic loading. To limit the scope, delamination growth under mode I fatigue has been investigated in the thesis.

The approach of the thesis is experimental. Delamination growth is characterized experimentally both on macroscopic and microscopic levels, as described in chapter 3. Fatigue tests were performed on double cantilever beam (DCB) specimens to investigate delamination growth behavior under different stress ratios. Specimens were made from cured laminates of M30SC/DT120 carbon/epoxy prepregs. Crack closure during delamination

growth was investigated using a clip gauge extensometer. The effect of fiber bridging was investigated by cutting bridging fibers during delamination growth experiments. Microscopy of the fracture surfaces was performed using scanning electron microscopy. Width tapered DCB (WTDCB) specimens were used for the delamination growth tests under fatigue with constant monotonic and cyclic load during delamination extension.

Results of the fatigue tests and microscopy are presented in chapter 4. The delamination growth rate has been related to the strain energy release rate (SERR). The SERR range has been defined such that it resembles the correct analogous to the stress intensity factor (SIF) range. For constant SERR range, the delamination growth rate is higher for higher stress ratios. Crack closure was observed to occur for the lowest stress ratio applied in the tests.

Fractographic analysis of the fracture surfaces revealed broken fibers, loose fibers, hackles and striations. The striations and hackles on the fracture surfaces of WTDCB specimens were quantitatively analyzed for different combinations of monotonic load and cyclic load amplitudes. It was observed that striation spacing increased with monotonic and cyclic load. The hackle length increased with monotonic load, but decreased with the cyclic load amplitude.

Crack closure and fiber bridging marginally explain the stress ratio effect on delamination growth, as discussed in chapter 5. Crack closure increases the effective minimum load at crack tip at the lower stress ratio only. This results in higher effective stress ratio at the crack tip. In this case, the SERR range was corrected for crack closure. By plotting delamination growth rate against corrected SERR range, the data shifted to the region with higher stress ratios. To illustrate the effect of crack closure in 3D representation, delamination growth rate was plotted against SERR range and maximum SERR. It was observed that the data corrected for crack closure shifted to the higher stress ratio region, while remaining on the same crack resistance surface.

It was further observed that fiber bridging decreases the delamination growth rate. The stress ratio remains the same. It was observed that fiber bridging affects both minimum and maximum loads during fatigue resulting in same stress ratio as without fiber bridging. In a 3D representation of delamination growth rate versus SERR range and maximum SERR, the data was observed to shift to the lower delamination growth rate region due to fiber bridging.

The experimental results showed that delamination growth is not a unique function of SERR range, but also depend on the stress ratio. This implies that delamination growth depends on both cyclic and monotonic loads. A two parameter model for delamination growth was developed based on the observation of the effect of cyclic and monotonic load on the fracture surfaces. Chapter 6 describes the mechanism of delamination growth and the development of the mechanistic two parameter model for delamination growth prediction. The two parameter components in the model are superimposed rather than multiplied in agreement with the superposition of the effects of cyclic and monotonic loads observed with microscopic features on the fracture surfaces. The two parameter model for delamination growth represents a crack resistance surface for the material in the 3D coordinates of delamination growth rate versus SERR range and maximum SERR.

The model has been implemented using data from the delamination growth experiments. The surface fitting tool of the commercial software MATLAB was used to obtain the equation. To validate the model, experimental data was taken from the literature. The predictions with the model and the reported experimental observations were observed to be in good agreement.

The current model is different from previous models in that the relation between delamination growth and correlating parameters is no longer a simple fit of the experimental data by regression. The fit is rather an educated fit based on the observed contribution of monotonic and cyclic load components on fracture mechanisms. The two parameters in the model are superimposed to describe contribution of the load components. In previous two parameter models the terms were multiplied without justification using the physics of delamination growth.

The conclusions of the thesis are summarized in chapter 8. It can be concluded that the effect of monotonic load on delamination growth is not fully explained by crack closure and fiber bridging. The delamination growth should be characterized using both monotonic and cyclic load components. These load components affects delamination growth at microscopic level independent of one another. The two parameter terms in the model are added in conjunction to the superposition of the effects of these parameters on microscopic features. It is concluded that the model can be extended to the delamination growth in different modes of fracture.

TABLE OF CONTENTS

Nomenclature	xiii
Abbreviations	xvii
Chapter 1 Introduction	1
Chapter 2 Literature review	7
2.1 Introduction.....	7
2.2 Classification of the investigations	8
2.2.1 Effect of stress ratio on mode I fatigue delamination growth.....	8
2.2.2 Effect of stress ratio on mode II fatigue delamination growth	15
2.2.3 Effect of stress ratio on mode III fatigue delamination growth.....	20
2.2.4 Effect of stress ratio on mixed fatigue delamination growth.....	21
2.3 Discussion.....	23
2.4 Conclusions.....	25
Chapter 3 Experiments and data evaluation	31
3.1 Introduction.....	31
3.2 Effect of stress ratio on mode I delamination growth.....	31
3.3 Crack closure effect on mode I delamination growth.....	36
3.4 Effect of fiber bridging on mode I delamination growth.....	37
3.5 Effect of width tapered DCB configuration.....	42
3.6 Microscopy of mode I fatigue delamination growth	45
Chapter 4 Experimental results	51
4.1 Introduction.....	51
4.2 Mode I fatigue delamination growth	51
4.2.1 Effect of stress ratio on mode I fatigue delamination growth.....	51

4.2.2 Crack closure effect on mode I fatigue delamination growth.....	54
4.2.3 Effect of fiber bridging on mode I fatigue delamination growth.....	57
4.2.4 Mode I fatigue delamination growth in WTDCB specimens	61
4.3 Microscopy results.....	64
4.3.1 SEM Examination of fracture surfaces for the effect of stress ratio.....	64
4.3.2 Roughness measurements of fracture surfaces using LCSM.....	66
4.3.3 In-situ SEM examination of the DCB specimen edges during monotonic loading	67
4.3.4 SEM examination of the edges of the DCB specimens after fatigue tests	69
4.3.5 Discussion of the SEM examination for the stress ratio effect.....	71
4.3.6 SEM examination of the fracture surfaces of WTDCB specimens	72
4.4 Discussion.....	80
Chapter 5 Effect of crack closure and fiber bridging on mode I fatigue delamination growth	83
5.1 Introduction.....	83
5.2 Effect of crack closure on mode I fatigue delamination growth	83
5.3 Effect of fiber bridging on mode I fatigue delamination growth.....	87
5.4 Conclusions.....	92
Chapter 6 Two parameter model for delamination growth.....	95
6.1 Introduction.....	95
6.2 Mechanism of delamination growth	96
6.2.1 Hackle formation during matrix decohesion	97
6.2.2 Striation formation during fiber matrix decohesion	99
6.3 Monotonic and cyclic load contribution related to fractographic features	100
6.4 Development of two-parameter model principle.....	101
6.4.1 Relation of hackle geometry with cyclic and monotonic loading.....	103

6.4.2	Relation of striation spacing with cyclic and monotonic loading	106
6.4.3	Macroscopic delamination growth	107
6.5	Implementation of the model	114
6.6	Verification of the model with data sets from the literature	122
6.6.1	Verification with data from Hojo's work	122
6.6.2	Verification with data from Bathias work	127
6.6.2	Verification with data from Mall's work	131
6.7	Discussion of the model	135
Chapter 7	Discussion	139
7.1	Aspects related to general delamination characterization	139
7.1.1	Opening modes	140
7.1.2	Monotonic and cyclic load contributions	144
7.1.3	Ply orientations	145
7.2	Delamination growth experiments	147
7.2.1	Selection of experiment and specimen	147
7.2.2	Considering fiber bridging	148
7.3	Fractographic evaluation	149
7.4	Characterization of delamination	150
7.4.1	Similitude principles	150
7.4.2	Plotting delamination resistance data	151
7.4.3	Boundaries of crack resistance surface in mode I delamination growth	151
7.4.4	Effects of crack closure and fiber bridging on delamination growth	152
7.5	Mechanistic model for delamination	153
7.6	Contribution of the present work to the stress ratio effect evaluation	154
7.7	Future prospects	155

Chapter 8 Conclusions	161
8.1 Characterization of delamination growth	161
8.2 Effect of crack closure and fiber bridging on delamination growth	161
8.3 Fractographic observations	161
8.4 Mechanistic model for delamination growth	162
Appendix A Strain energy release rate.	163
A.1 Strain energy release rate	163
A.2 Derivation of strain energy release rate range ΔG_s	164
A.3 Strain energy release rate range in case of crack closure.....	165
Appendix B Fatigue delamination growth tests results.....	167
B.1 Effect of stress ratio on delamination growth rate	167
B.2 Crack closure tests.....	169
B.3 Fatigue delamination growth tests for fiber bridging effect investigation.....	171
B.4 Delamination growth tests under constant G_{max} and constant ΔG_s using width tapered DCB specimens.....	176
Appendix C Microscopy results	187
C.1 Hackles.....	187
C.2 Striations	200
